Partition disks Partitioning a hard disk means that the hard disk is split into logical divisions that represent hard disk storage units, called partitions. Disk partitions are often used to increase disk space. Each partition represents one of the hard disk's internal divisions. There is no physical difference between each partition. A disk partition does not physically change the form or size of the disk. For example, an external hard disk could be formatted to have three partitions. However, if the disk is later connected to another computer, it may be possible for the operating system to read and operate on one partition, but have issues accessing other partitions. Partitioning Partitioning a hard disk is done with the Disk Management console that is included with Windows operating systems. The Disk Management console provides tools to set up and format disk partitions, delete partitions, move partitions around, restore partitions, and repair disk errors. Prior to Windows Vista, the partitioning operations were performed with the Windows XP Disk Management console. In Windows XP, the Disk Management console shows both the partitions of a disk that are active and inactive. While performing partitioning, the following steps are taken: With Windows XP, the partitioning was done through the Disk Management console. This operation created a new partition in unused space of the disk and marked the disk as active. A new partition was created by clicking "New Partition" in the Disk Management console. In Windows XP, the new partition was shown on a new tab in the Disk Management console. With Windows Vista, the partitioning was done through the Disk Management console or by using the Disk Management console's partition tools. The installation DVD also includes partitioning tools that can be used to format and partition a hard 2d92ce491b
