is simple to implement on Linux, OS X and Windows (and even easier than on ZFS), it would be pretty difficult to securely implement on iOS, no matter how many clever techniques you may think of. QSifre supports unlimited users and accounts but allows you to set a security password when you sign-up. It's a simple and straightforward password vault. It may not be as powerful as other password managers such as 1Password, LastPass or Dashlane but it should be sufficient for most people. Free
Version: You can create as many users as you want. (You can't delete or add users) By default, QSifre will store all of your accounts information in LocalStorage. If this data is

deemed sensitive, the option to store it in a database is available. Its iPhone app is free but is currently inactive as of 2017. A: Sigil, while also a password manager, provides better security. More info: Q: Java JTextArea without scrolling bar I have an application that has a text area, when typing in the text area, the height changes. I have heard about the scroll bars, but i don't want any scroll bars for my text area. How can I do this? A: The functionality you're looking for is called "antialiasing". You probably know how it works: The antialiasing feature on most LCD monitors and on some TV

sets is configured with a "soft" refresh rate. Soft refresh, also called de-interlacing, is a technique where two partial frames of the image are displayed on the screen instead of the regular three complete frames. The two partial frames combine to make up the full frame. Basically, the color of pixels is continuously changed.

QSifre is a tool with the purpose of protecting accounts and details using AES 256. QSifre works by creating a key from user-defined values such as user name, password, email and other information. All accounts are protected by means of using the same key in decryption, even when a user transfers account from one application to the next. QSifre is free, and all available information about the program and its features can be found by accessing the program's page on the Internet. Q: Is it possible to make a fully automated

application to trace back a process in the call stack? I found this in an article today. How the process starts is obfuscated. There is no active execution so the trace back is not trivially obvious. I tried to follow the link pointing to the original paper but it seems the author is not available to comment. Did anyone know if there is an easy to reverse engineer stack trace in his obfuscated process? Or is there another technique of obfuscating the call stack? A: Obfuscated: The author creates an obfuscated 'call stack' in the encrypted program. All stacktraces use one base

address in the file. Whenever the program calls another function, the program writes a pointer to the new function to the stack, then jumps to the first instruction of the function. Pointer to new function code: when the obfuscator detects the jmp instruction at the entry of a function, it will scan backwards to the next jmp instructions in the same function, and create a jump counter. Each jmp instruction is encoded with the amount of jump steps, and a position to jump. Whenever the jump counter hits its limit, it replaces the jmp with a call instruction which takes the jump counter

as the target address. if the obfuscated program calls a function which writes a return value to a function, it will write the return value to the stack to make the stack trace almost undecipherable. when there's no return value on the stack, it will use the return address to jump to an address injected by the author on every function.

Pointer to return value: When the obfuscator detects a pointer on the stack, it will scan backwards to the next byte of the same function. for every byte that it encounters, it will check if the byte value is a pointer. if it is, it will update the jump counter, then create a

jump destination of the jump counter
